Factor analysis (FA) Q8

3, 4 and 5 factors are acceptable. Shown are only 3 and 4 factors, as 5 appear too many for 9 variables.

- Factor1 (Games): playgamesfriends, plagamesstranger, playgamesalone
- Factor2 (Spare time): killtime, browsenoreason, beentertained

Downloadmusic appears to be unrelated to the above identified latent variables.

FA Q10

Minimum 3 factors required. 4 factors are too many.

Figure 1: FA loadings

Figure 2: FA unique variance

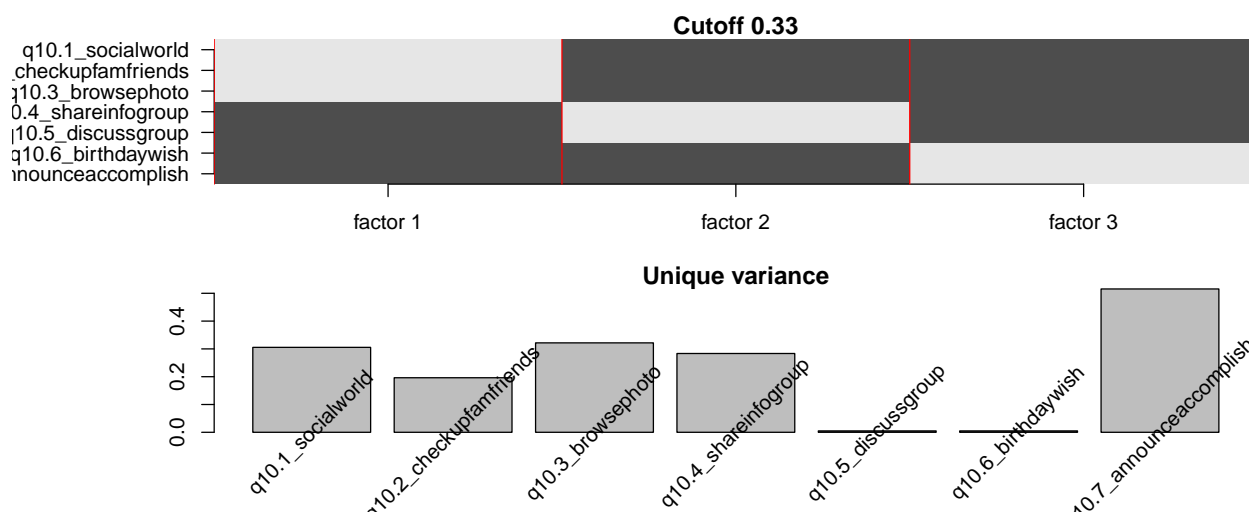

Figure 3: FA loadings and unique variance

Figure 4: Counts

Figure 5: FA loadings

Analysis of Q19

Acceptable factors are 2 to 7. Regardless of the number of factors the isel questions' subscales (Tangible, Appraisal, Belonging and Self-esteem) do not appear to be constructing independent latent variables.

FA Q20

2 or 3 factors

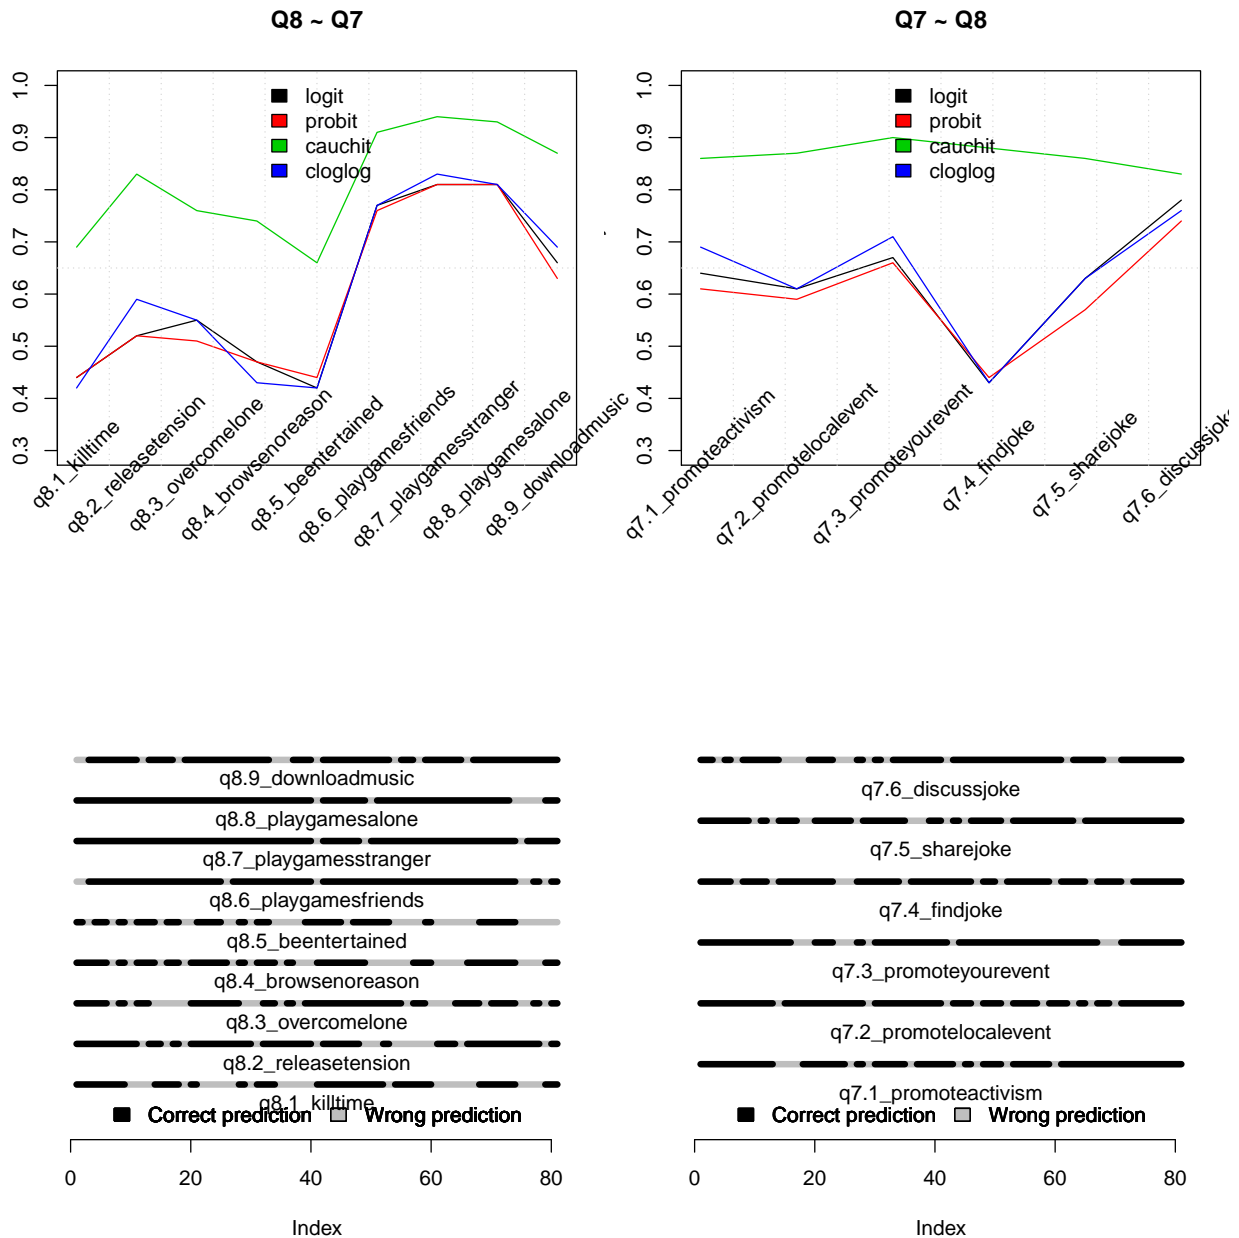

Predictive models

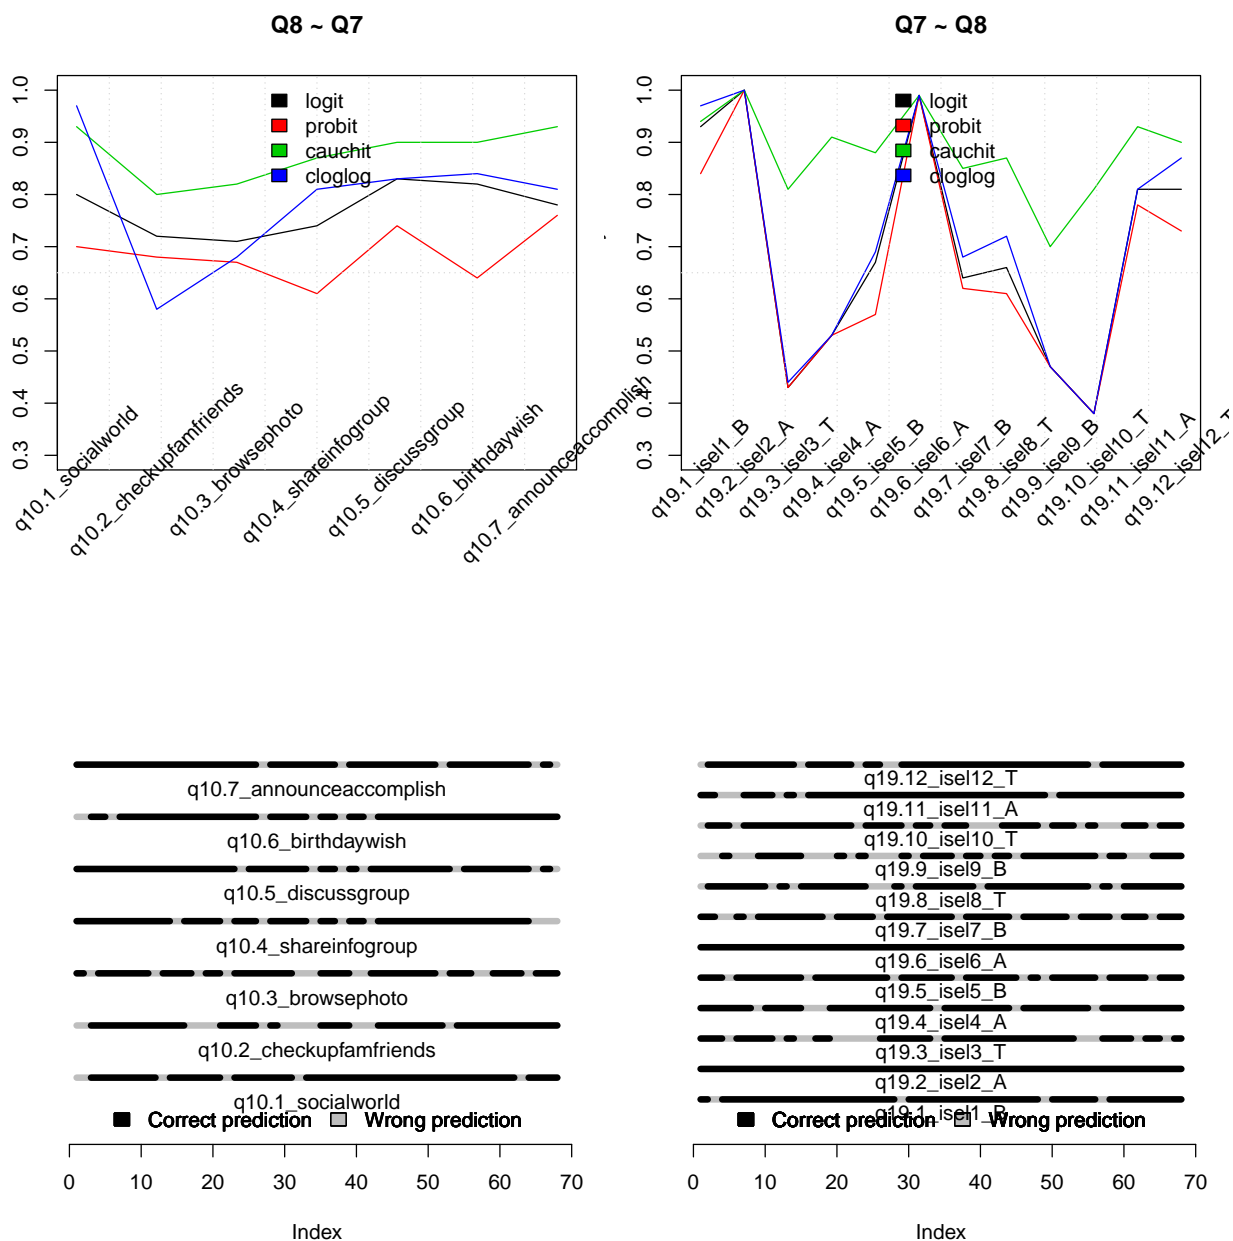

Q8 and Q7

The first two plots show the prediction accuracy followed by the actual prediction (true/false).

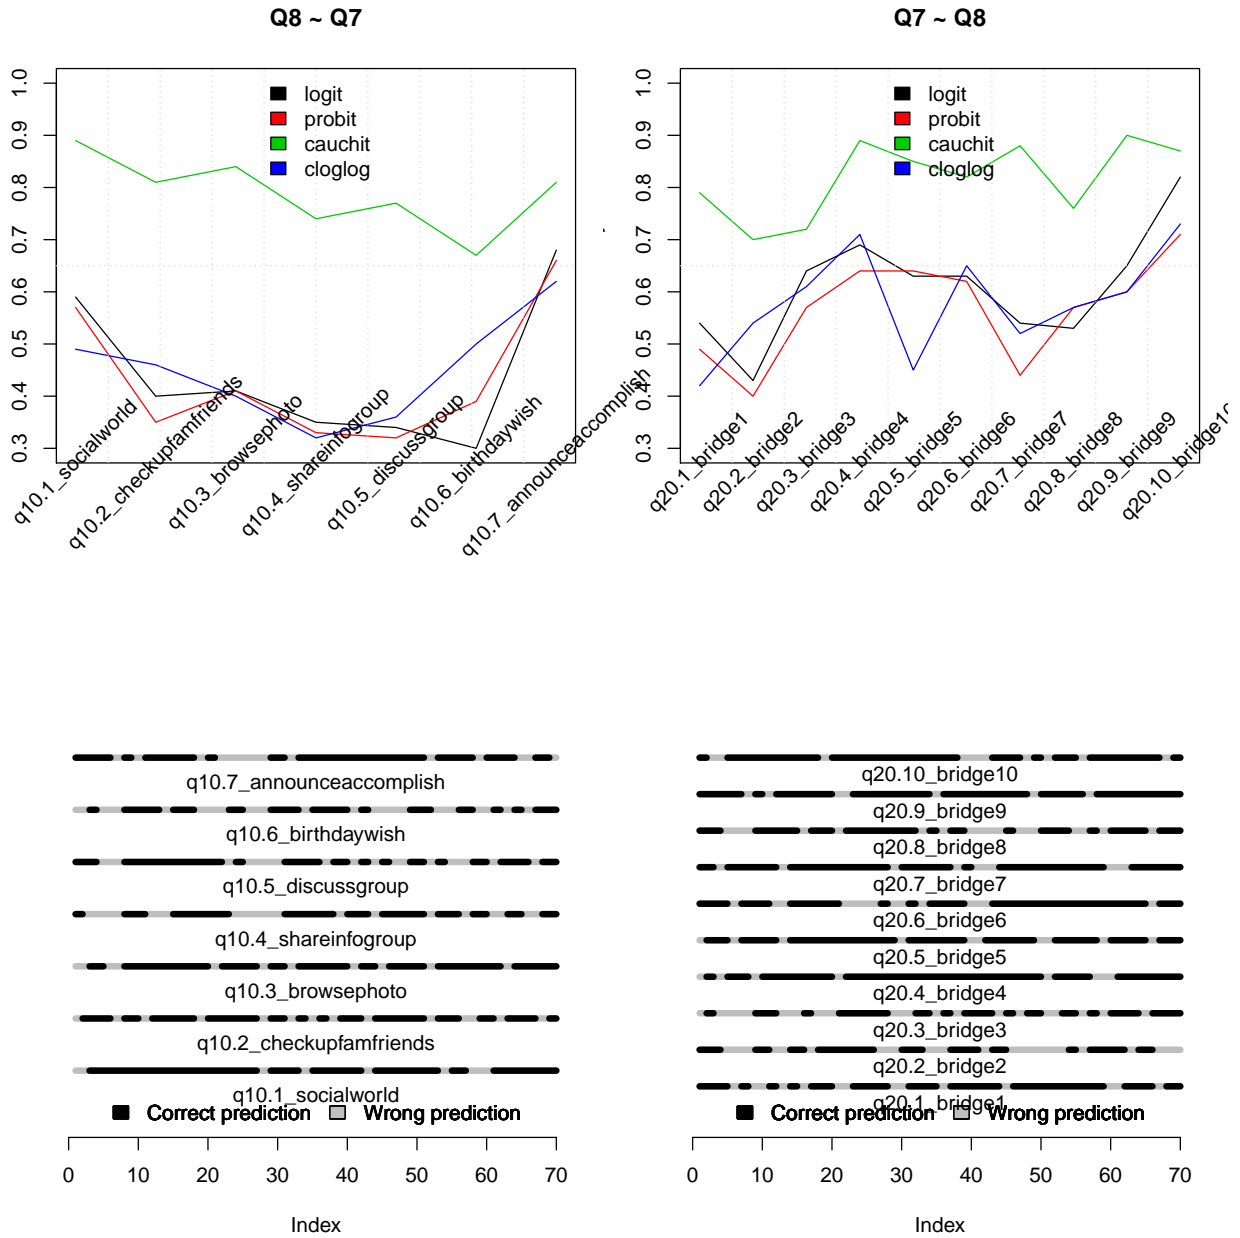

Q10 and Q19

The first two plots show the prediction accuracy followed by the actual prediction (true/false).

Q10 and Q20

The first two plots show the prediction accuracy followed by the actual prediction (true/false).

Further

- Factor analysis can be extended to include other questions and subquestions
- Particular hypothesis could be tested using CFA
- Alternative predictive models for latent variables can be constructed, potentially for mixtures of questions
- Cauchit link binomial GLMs appear to be fitting best. Alternatively, one could investigate negative binomial GLMs
